

ABSTRACT

The present device is utilized by equestrian riders to maintain their horse's forehead vertical with the ground. It is made of plastic and readily attaches to the bridle on top of the horse's head, between the ears. A colored indicator is visible to the rider through an opening in the device and lets the rider know if the animal's head is vertical with the ground or if the nose is back or away from the animal's body. This device will aid the rider and horse to learn how to position and maintain the animals forehead vertical with the ground.
